

1.

2. The web page is a site that is entirely used for a business or a company to sell its product and inform potential customers of the Brand, offering customer services showing everything they can do or information about the product.
Meanwhile the blog or weB Log is an informative site or personal diary made by one person or a group, used to share opinions about a topic like technology or fashion.

3.

1. PAN – Personal Area Network

Range: Very short (a few meters)

Used for: Connecting personal devices (e.g., phone, laptop, Bluetooth headset)

2. LAN – Local Area Network

Range: Small area like a room, building, or school

Used for: Connecting computers in a local environment (home, office, classroom)

Example: School computer lab or Wi-Fi at home.

3. WLAN – Wireless Local Area Network

Range: like LAN but wireless

Used for: Wi-Fi connections using wireless signals instead of cables.

Example: Wi-Fi network in your house or a coffee shop.

4. MAN – Metropolitan Area Network

Covers a city or large campus Connecting multiple LANs across a city.

Example: A city's traffic light system or a university network with multiple buildings.

5. WAN – Wide Area Network

Range: Covers large geographic areas (countries or continents)

Used for: Connecting LANs and MANs over long distances.

Example: The Internet is the biggest WAN in the world.

6. SAN – Storage Area Network

Used for: High-speed connection between data storage devices and servers.

Example: A company using SAN to store large databases safely and quickly.

7. VPN – Virtual Private Network

Not a physical network, but a secure "tunnel" over the Internet

Used for: Protecting privacy and accessing restricted content.

Example: Using a VPN to access blocked websites or hide your IP address.

4.

1. Bus Topology

Are All devices who are connected to a single central cable it is Easy to install and uses less cable than other topologies. If the main cable fails, the whole network goes down. Limited number of devices.

2. Star Topology

Are all devices who are connected to a central device (like a switch or hub). Easy to manage. If one device fails, the rest continues to work. If the central hub fails, the entire network fails. Uses more cable than bus topology.

3. Ring Topology

Each device is connected to two other devices, forming a circle or "ring." Data moves in one direction, reducing collisions. One broken connection can affect the whole network. Difficult to troubleshoot.

4. Mesh Topology

Every device is connected to every other device. High reliability. If one link fails, there are other paths. Expensive and complex to install. Requires lots of cables and ports.

5. Tree Topology

A combination of star and bus topologies — arranged in a hierarchical way.

Scalable (good for large networks). Easy to manage groups of devices. If the main trunk fails, parts of the network go down with complex cabling.

6. Hybrid Topology

A mix of two or more different topologies, Flexible and scalable and can be designed for specific needs but it can be expensive and complex and difficult to design and maintain.
